COMP1531

Design - Software Complexity

Lecture 9.2

Author(s): Hayden Smith

(Download as PDF)

In This Lecture

- Why? 🤔
 - We need a material way to be able to understand and have conversations about how complex software is
- What?
 - Accidental V Essential Complexity
 - Cyclomatic Complexity Measurements

What Is Software Complexity?

Any ideas?

What Is Software Complexity?

- A famous paper from 1986:
 - *No Silver Bullet Essence and Accident in Software Engineering* by Fred Brooks
- Described software complexity by dividing it into two categories *essential* and *accidental*.
- Further conclusions of the paper are much debated

Complexity that is inherent to the problem.

For example, if the user or client requires the program to do 30 different things, then those 30 things are essential.

Complexity that is not inherent to the problem.

For example, generating or parsing data in specific formats.

Fundamentally can't be removed, but can be managed with good *software design*.

Can be somewhat mitigated by engineering decisions; e.g. smart use of libraries, standards, etc.

Hard to remove entirely.

Open Questions

- Is there a concrete process for distinguishing accidental and essential complexity?
- How much of the complexity of modern software is accidental?
- To what degree has or will accidental complexity be removed in future?

33 How Can We Measure Software Complexity?

😂 How Can We Measure Software Complexity?

- Coupling
- Cohesion
- Cyclomatic Complexity

- A measure of how closely connected different software components are.
- Usually expressed as a simple ordinal measure of "loose" or "tight".
- For example, web applications tend to have a frontend that is loosely coupled from the backend.
- Loose coupling is good

Cohesion

- The degree to which elements of a module belong together.
- Elements belong together if they're somehow related.
- Usually expressed as a simple ordinal measure of "low" or "high".
- High cohesion is good
- Read more here

- A measure of the branching complexity of functions.
- Computed by counting the number of linearly-independent paths through a function.

To compute:

- 1. Convert function into a control flow graph
- 2. Calculate the value of the formula

$$V(G) = e - n + 2$$

where e is the number of edges and n is the number of nodes

```
function foo() {
 if (A())
B();
} else {
C();
```

$$V(G) = 4 - 4 + 2 = 2$$

```
function foo() {
 if (A()) {
   B();
 } else {
 if (C()) {
     D():
```

$$V(G) = 6 - 5 + 2 = 3$$

```
function foo() {
 while (A()) {
   B();
C();
```

$$V(G) = 3 - 3 + 2 = 2$$

```
function day_to_year(days) {
     let year = 1970
 3
     while (days > 365) {
 4
       if (is_leap_year(year)) {
 5
         if (days > 366) {
 6
           days -= 366;
 8
           year += 1;
 9
     } else {
10
         days -= 365;
11
12
         year += 1;
13
     }
14
15
16
     return year;
17 }
```

$$V(G) = 8 - 6 + 2 = 4$$

```
1 function day_to_year(days) {
     let year = 1970
 3
     while (days > 0) {
 4
 5
       if (is_leap_year(year)) {
         days -= 366;
 6
       } else {
         days -= 365;
       year += 1;
11
12
13
     return year - 1;
14 }
```

$$V(G) = 7 - 6 + 2 = 3$$

A simple understandable measure of function complexity.

Some people argue 10 should be the maximum cyclomatic complexity of a function where others argue for 8.

Opening the property of the

- Assumes non-branching statements have no complexity.
- Keeping cyclomatic complexity low encourages splitting functions up, regardless of whether that really makes the code more understandable.

Automatic Calculation

Depending on the programming language, sometimes there are tools that exist to automatically calculate it.
