#### **COMP1531**

#### Projects - Continuous Integration

Lecture 3.2

Author(s): Hayden Smith

(Download as PDF)

#### In This Lecture

- Why? 🤔
  - To scale multi-user software projects, we need automated ways to integrate and test code
- What?
  - Continuous Integration
  - Pipelines
  - Runners

**Continuous Integration**: Practice of automating the integration of code changes from multiple contributors into a single software project.

Or in more concrete terms: Helping make merges into master more **frequent** and **stable**.

Typically continuous integration consists of a series of operations that are executed on any commit that is pushed to the repository, for example:

- Building (not applicable in JS)
- Testing
- More (in next lectures).

i.e. To oversimplify, continuous integration allows us to:

- 1. Automatically run npm run test (and more) on every commit.
- 2. Get a visual "OK"/"Not OK" summary of this on gitlab, including more details.

# Setting It Up

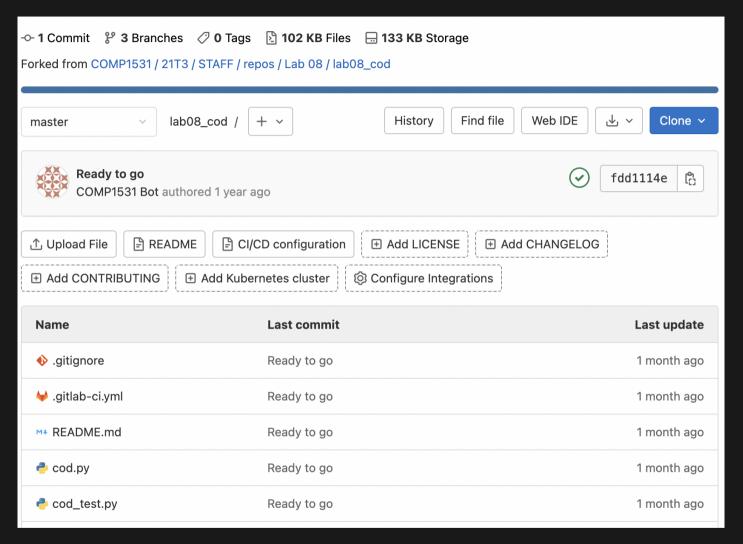

Every git website has it's own way of handling continuous integration. With gitlab, it's the addition of a .gitlab-ci.yml file within the root of your git repository. An example that just does testing would be:

```
image: comp1531/basic:latest
   cache:
    paths:
 5
       - node_modules
 6
   stages:
     - checks
 8
 9
   sanity:
   stage: checks
11
12 script:
       - echo 'Hello!'
13
```

3.2\_gitlab-ci\_basic.yml

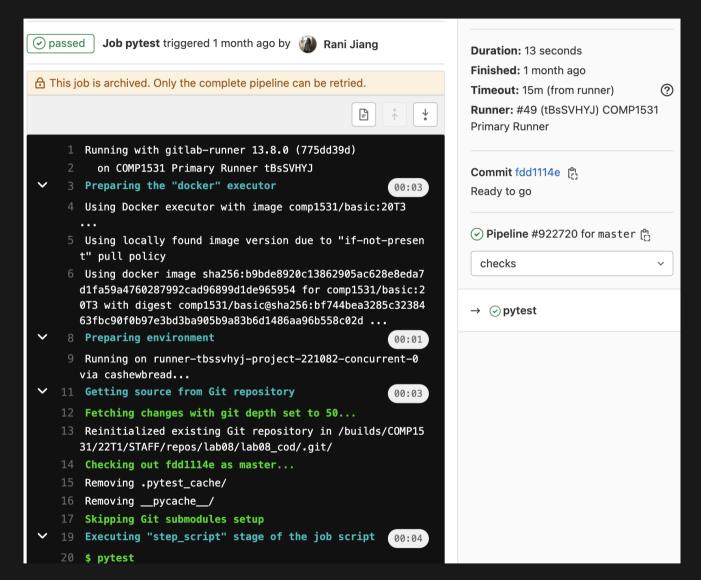

Let's try and add this to a repo.

See the tick? This tick indicates that some process was run from the last commit. It uses .gitlab-ci.yml to figure out what to run. You can click the tick.

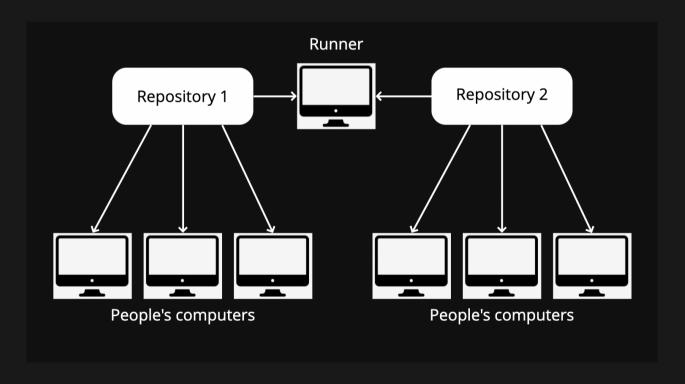

This is what we call the **pipeline** - a summary of what was run.

## **How It Works**

When a commit is pushed, all of the code in that commit is taken by another computer (or "runner") and has the .gitlab-ci.yml instructions run on it.

#### **Architecture**

## **How It Works**

A runner really is just another computer whose sole job it is to run these "pipelines".

For more commercial products **github** and **bitbucket**, they have an array of runners that are used for people with git repositories. These tend to have free usage limits and then they start charging.

For **gitlab**, runners are not build in, but we've setup a runner for you. This runner runs on any .gitlab-ci.yml configuration that is pushed within the COMP1531 repos on gitlab.

Now let's add **jest** to the pipeline!

```
1 image: comp1531/basic:latest
2
3 cache:
4  paths:
5   - node_modules
6
7 stages:
8  - checks
9
10 testing:
11  stage: checks
12  script:
13  - npm run test
```

3.2\_gitlab-ci\_test.yml

## **Configuring**

Normally you would have an extra step here for npm install!

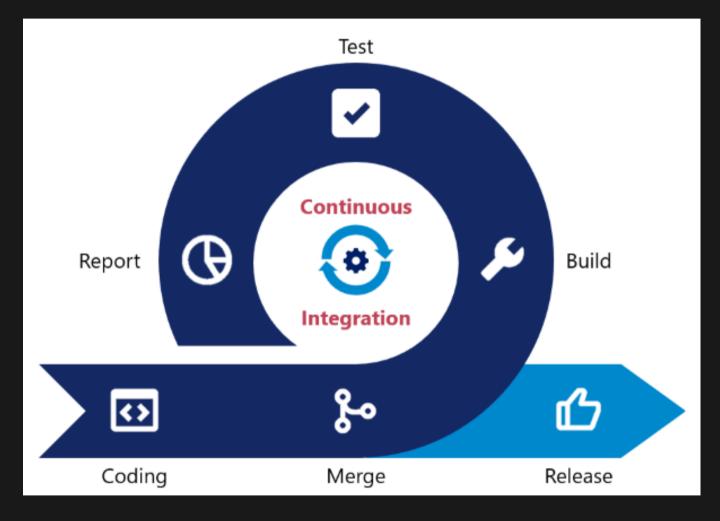

```
1 testing:
2  stage: checks
3  script:
4  - npm install
5  - npm run test
```

In summary, continuous integration assists us in making frequent code changes, because we can:

- 1. Write tests
- 2. Write implementation
- 3. Push to gitlab + add merge request
- 4. Make sure we have the green tick
- 5. Merge in

Confidence!

An important rule to follow is that your master branch should ALWAYS be green. No code should be merged into it unless you're getting the green tick.
